

# Bayesian Linear Regression: Complete Hand Calculation Example

## Problem Setup

We'll work through a simple linear regression problem by hand:

- Model:  $y = a + bx + \epsilon$
- Prior:  $w \sim N(\theta, (1/\alpha)I)$  where  $w = [a, b]^T$
- Noise:  $\epsilon \sim N(0, 1/\beta)$

## Data

We have just 2 data points to keep calculations manageable:

- Point 1:  $(x_1, y_1) = (0, 1)$
- Point 2:  $(x_2, y_2) = (1, 3)$

## Hyperparameters

- $\alpha = 1$  (prior precision)
- $\beta = 4$  (noise precision, so  $\sigma^2 = 0.25$ )

## Step 1: Set Up Design Matrix

The design matrix  $\Phi$  includes a column of ones (for intercept) and x values:

$$\Phi = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$$

## Step 2: Set Up Prior

Prior distribution:  $w \sim N(m_0, S_0)$

- Mean:  $m_0 = [\theta, \theta]^T$
- Covariance:  $S_0 = (1/\alpha)I = (1/1)I = I$

$$S_0 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

Inverse:  $S_0^{-1} = \alpha I = I$

### Step 3: Calculate $\Phi^T \Phi$

$$\Phi^T = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$

$$\Phi^T \Phi = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \times \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 \times 1 + 1 \times 1 & 1 \times 0 + 1 \times 1 \\ 0 \times 1 + 1 \times 1 & 0 \times 0 + 1 \times 1 \end{bmatrix} = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$$

### Step 4: Calculate Posterior Covariance

Formula:  $S = (S_0^{-1} + \beta \Phi^T \Phi)^{-1}$

First, calculate  $S_0^{-1} + \beta \Phi^T \Phi$ :

$$S_0^{-1} + \beta \Phi^T \Phi = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + 4 \times \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + \begin{bmatrix} 8 & 4 \\ 4 & 4 \end{bmatrix} = \begin{bmatrix} 9 & 4 \\ 4 & 5 \end{bmatrix}$$

Now invert this  $2 \times 2$  matrix:

$$S^{-1} = \begin{bmatrix} 9 & 4 \\ 4 & 5 \end{bmatrix}$$

$$\det(S^{-1}) = 9 \times 5 - 4 \times 4 = 45 - 16 = 29$$

$$S = (1/29) \times \begin{bmatrix} 5 & -4 \\ -4 & 9 \end{bmatrix} = \begin{bmatrix} 5/29 & -4/29 \\ -4/29 & 9/29 \end{bmatrix}$$

Numerically:

$$S = \begin{bmatrix} 0.172 & -0.138 \\ -0.138 & 0.310 \end{bmatrix}$$

### Step 5: Calculate $\Phi^T y$

$$y = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

$$\Phi^T y = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \times \begin{bmatrix} 1 \\ 3 \end{bmatrix} = \begin{bmatrix} 1 \times 1 + 1 \times 3 \\ 0 \times 1 + 1 \times 3 \end{bmatrix} = \begin{bmatrix} 4 \\ 3 \end{bmatrix}$$

## Step 6: Calculate Posterior Mean

Formula:  $m = S(S_0^{-1}m_0 + \beta\Phi^T y)$

Since  $m_0 = 0$ , we have:

$$m = S(\beta\Phi^T y) = S \times 4 \times \begin{bmatrix} 4 \\ 3 \end{bmatrix} = S \times \begin{bmatrix} 16 \\ 12 \end{bmatrix}$$

$$m = \begin{bmatrix} 5/29 & -4/29 \end{bmatrix} \times \begin{bmatrix} 16 \\ 12 \end{bmatrix} = \begin{bmatrix} (5 \times 16 - 4 \times 12)/29 \\ (-4 \times 16 + 9 \times 12)/29 \end{bmatrix} = \begin{bmatrix} (80-48)/29 \\ (-64+108)/29 \end{bmatrix} = \begin{bmatrix} 32/29 \\ 44/29 \end{bmatrix}$$

Numerically:

$$m = \begin{bmatrix} 1.103 \\ 1.517 \end{bmatrix}$$

## Interpretation

The posterior mean gives us:

- Intercept (a): 1.103
- Slope (b): 1.517

So our estimated line is:  $y = 1.103 + 1.517x$

## Step 7: Make a Prediction

Let's predict at  $x^* = 0.5$ :

$$\phi^* = [1, 0.5]$$

### Mean Prediction

$$\mu^* = \phi^{*T} m = [1, 0.5] \times \begin{bmatrix} 1.103 \\ 1.517 \end{bmatrix} = 1.103 + 0.5 \times 1.517 = 1.862$$

### Prediction Variance

Function variance:

$$\sigma^2_x = \phi^{*T} S \phi^*$$

First calculate  $S\phi^*$ :

$$S\phi^* = \begin{bmatrix} 0.172 & -0.138 \end{bmatrix} \times \begin{bmatrix} 1 \\ 0.5 \end{bmatrix} = \begin{bmatrix} 0.172 - 0.069 \\ -0.138 + 0.155 \end{bmatrix} = \begin{bmatrix} 0.103 \\ 0.017 \end{bmatrix}$$

Then:

$$\sigma^2_x = \begin{bmatrix} 1, & 0.5 \end{bmatrix} \times \begin{bmatrix} 0.103 \\ 0.017 \end{bmatrix} = 0.103 + 0.5 \times 0.017 = 0.103 + 0.0085 = 0.1115$$

Predictive variance (including noise):

$$\sigma^2_y = \sigma^2_x + 1/\beta = 0.1115 + 1/4 = 0.1115 + 0.25 = 0.3615$$

Standard deviation:  $\sigma_y = \sqrt{0.3615} = 0.601$

## Step 8: 95% Credible Intervals

For the parameters:

$$\begin{aligned} \text{a: } & 1.103 \pm 1.96 \times \sqrt{0.172} = 1.103 \pm 1.96 \times 0.415 = 1.103 \pm 0.813 \\ & \rightarrow [0.290, 1.916] \end{aligned}$$

$$\begin{aligned} \text{b: } & 1.517 \pm 1.96 \times \sqrt{0.310} = 1.517 \pm 1.96 \times 0.557 = 1.517 \pm 1.092 \\ & \rightarrow [0.425, 2.609] \end{aligned}$$

For the prediction at  $x^* = 0.5$ :

$$\begin{aligned} y^*: & 1.862 \pm 1.96 \times 0.601 = 1.862 \pm 1.178 \\ & \rightarrow [0.684, 3.040] \end{aligned}$$

## Summary

From just 2 data points:

- Estimated line:  $y = 1.103 + 1.517x$
- Prediction at  $x=0.5$ :  $1.862 \pm 1.178$  (95% CI)

- Intercept uncertainty:  $\pm 0.813$
- Slope uncertainty:  $\pm 1.092$

The calculations show how:

1. Prior information ( $S_0$ ) combines with data information ( $\beta\Phi^T\Phi$ )
2. More data points would make  $S^{-1}$  larger, reducing posterior variance
3. Predictions include both parameter uncertainty and noise

## Verification Check

Let's verify our line passes near the data:

- At  $x=0$ :  $y = 1.103$  (actual: 1) ✓
- At  $x=1$ :  $y = 1.103 + 1.517 = 2.620$  (actual: 3) ✓

The slight differences are expected due to noise and prior influence.
